Lambda functions

1. **Lambda example**

Write down a 'function recipe' and apply it directly,
without creating a 'named function':

```
[] (float x,float y) -> float {
  return x+y; } ( 1.5, 2.3 )
```

Store lambda in a variable:

```
auto summing =
  [] (float x,float y) -> float {
  return x+y; };
cout << summing ( 1.5, 2.3 ) << endl;
```

2. Lambda syntax

```
[capture] ( inputs ) -> outtype { definition };
[capture] ( inputs ) { definition };
```

- The square brackets are how you recognize a lambda
- Inputs: like function parameters
- Result type specification -> *outtype*:
  can be omitted if compiler can deduce it;
- Definition: function body.

3. Assign lambda to variable

```
auto f = [] (double x) -> double { return 2*x; };
y = f(3.7);
z = f(4.9);
```

- This is a variable declaration.
- Uses `auto` for technical reasons
- See different approach below.

Exercise 1

The Newton method (see HPC book) for finding the zero of a function f, that is, finding the x for which $f(x) = 0$, can be programmed by supplying the function and its derivative:

```cpp
double f(double x) { return x*x-2; };
double fprime(double x) { return 2*x; };
```

and the algorithm:

```cpp
double x{1.};
while ( true ) {
  auto fx = f(x);
  cout << "f( " << x << " ) = " << fx << "\n";
  if (abs(fx)<1.e-10 ) break;
  x = x - fx/fprime(x);
}
```

Rewrite this code to use lambda functions for f and g.

You can base this off the file `newton.cxx` *in the repository*

4. Lambdas as parameter: the problem

Lambdas are in a class that is dynamically generated, so you can not write a function that takes a lambda as argument, because you don't have the class name.

```cpp
void do_something( /* what? */ f ) {
    f(5);
}
int main() {
    do_something
      ( [] (double x) { cout << x; } );
}
```

5. Lambdas as parameter: the solution

```
#include <functional>
using std::function;
```

With this, you can declare parameters by their signature:

```
double find_zero
   ( function< double(double) > f,
     function< double(double) > fprime ) {
```

Exercise 2

Rewrite the Newton exercise above to use a function with prototype

```
double root = find_zero( f,g );
```

Call the function directly with the lambda functions as arguments, that is, without assigning them to variables.

6. Capture parameter

Capture value and reduce number of arguments:

```
int exponent=5;
auto powerfive =
  [exponent] (float x) -> float {
    return pow(x,exponent); };
```

Now `powerfive` is a function of one argument, which computes that argument to a fixed power.

```
Code:

cout << "To the power "
    << exponent << endl;
for (float x=1.; x<=5.; x+=1.)
  cout << x << ":" << powerfive(x) <<
    endl;
```

```
Output
[func] lambdait:

To the power 5
1:1
2:32
3:243
4:1024
5:3125
```

Exercise 3

Extend the newton exercise to compute roots in a loop:

```
for (int n=2; n<=8; n++) {
  cout << "sqrt(" << n << ") = "
       << find_zero(
/* ... */
                    )
       << "\n";
```

Without lambdas, you would define a function

```
double to_the_nth( double x,int n );
```

However, the `find_zero` function takes a function of only a real argument. Use a capture to make `f` dependent on the integer parameter.

Exercise 4

You don't need the gradient as an explicit function: you can approximate it as

$$f'(x) = \bigl(f(x + h) - f(x)\bigr)/h$$

for some value of h.

Write a version of the root finding function

```
double find_zero( function< double(double)> f, double h=.001 );
```

that uses this. Do not reimplement the whole newton method: instead create a lambda for the gradient and pass it to the function `find_zero` you coded earlier.

7. Capture by value/reference

Normal capture is by value:

```
Code:

int one=1;
[one] ( int input ) -> void {
  cout << input+one << endl;
} (5);
```

```
Output
[func] lambdavalue:

6
```

Capture by reference:

```
Code:

[&one] ( int input ) -> void {
  one++;
  cout << input+one << endl;
} (5);
cout << "one is now: " << one << endl;
```

```
Output
[func] lambdareference:

7
one is now: 2
```

8. **Capture a reduction variable**

This mechanism is useful

```
int count=0;
auto count_if_f = [&count] (int i) {
      if (f(i)) count++; }
for ( int i : int_data )
  count_if_f(i);
cout << "We counted: " << count;
```

9. **Capture by reference**

Capture variables are normally by value, use ampersand for reference. This is often used in `algorithm` header.

```
Code:

  vector<int> moreints{8,9,10,11,12};
  int count{0};
  for_each
    ( moreints.begin(),moreints.end(),
      [&count] (int x) {
        if (x%2==0)
          count++;
      } );
  cout << "number of even: " << count
    << endl;
```

```
Output
[stl] counteach:

number of even: 3
```
